

## DEFINITION OF EXOTIC NUISANCE ALIEN INVASIVE SPECIES AND NATIVE INDIGENOUS SPECIES

*From Maine DEP website <http://www.maine.gov/dep/blwq/topic/invasives/invtermplant.htm>*

Discussions of Invasive Aquatic Plants include many words we all recognize, but the context can be unfamiliar and confusing when applied to plants. In addition to the common usage, biologists use these terms to describe the ecological status of plant or animal populations and how they fit into a particular geographical region. Some terms are used interchangeably, such as nuisance and invasive, both with a negative connotation. Four categories (Binggeli 1994) serve to cover the concepts used to describe the status and the distribution of a particular species.

1. **Native, Indigenous:** species naturally occurring or originating in a geographical region since prehistorical time;
2. **Introduced, Alien, Exotic:** deliberate or accidental release of a species into an area in which it has not occurred in historical times;
3. **Invasive:** the establishment of self-regenerating and spreading populations of a naturalized species in a free-living state in the wild, takes possession and may affect injuriously;
4. **Nuisance, Noxious, Weed:** any plant, either native or introduced, with a harmful or destructive influence on existing natural communities, interfering with the objectives or requirements of people.

These categories apply to biological communities, which are always evolving or changing due to fluctuating environmental conditions. Some species may be considered invasive if they occur in Maine but have been transported between watersheds and their introduction has caused detrimental effects to existing populations (e.g. introduction of white perch to brook trout waters has severely curtailed the beneficial values of brook trout in the affected waters). Some species in Maine fit into one or several of these categories, for example:

- Variable milfoil: a common plant in its native range, is invasive and a nuisance when spread to new waterbodies
- Bladderwort: a common native aquatic plant that is occasionally considered a nuisance
- Purple Loosestrife: a rapidly spreading exotic invasive in wetland habitat
- Brook Trout: a desirable native that is not a nuisance
- Brown Trout: an introduced species that is not invasive or considered a nuisance
- Gold Fish or Carp: exotics that are also considered noxious invasives

Binggeli, P. (1994) Misuse of terminology and anthropomorphic concepts in the description of introduced species. Bull. Brit. ecol. Soc. 25, 10-13.

<http://members.tripod.co.uk/WoodyPlantEcology/invasive/terminology.htm>

## DEFINING THE TERM “INVASIVE SPECIES”

*Excerpted with permission from a letter to Lori Williams, Executive Director, National Invasive Species Council, U.S. Department of the Interior, from E. Shippen Bright, Interim Chairman, Invasive Species Advisory Committee, dated April 23, 2004*

At a number of recent policy forums, the ambiguity of the term “invasive species” has been cited as a reason for delaying new federal programs to combat the problem. Confusion over this particular term is understandable, given the globally diverse terms used in describing the issue. However, the use of the term “invasive species” and its meaning pertaining to U.S. federal programs within the Invasive Species Advisory Committee (ISAC) and the 2001 National Management Plan for Invasive Species (NMP) has been debated and agreed upon. While some areas remain unclear or “gray”, they need not hinder action to prevent and control those organisms that clearly fall within the boundaries of the NMP definitions. This letter is to summarize these important distinctions, hoping that the member agencies of the National Invasive Species Council (NISC) can quickly and decisively respond to programmatic criticisms stemming from definitional concerns, allowing discussion to proceed on more important questions of policy.

Executive Order 13112, which established NISC, utilizes the terms “alien,” “invasive” and “native” species. It defines the term “*alien species*” as:

*“any species, including its seeds, eggs, spores or other biological material capable of propagating that species, that is not native to that [particular] ecosystem.”*

The order defines “*invasive species*” as:

*“an alien species whose introduction does or is likely to cause economic or environmental harm or harm to human health.”*

It further defines “*native species*” as:

*“a species that, other than as a result of an introduction, historically occurred or currently occurs in that [particular] ecosystem.”*

In continuing this convention, the NMP clarifies the difference between “alien” and “invasive” by stating that the latter are those that cause or are likely to cause harm to the nation’s economy, environment, or public health. It provides a set of examples to illustrate the distinctions between these concepts, and calls for a clear set of screening criteria which will consider potential societal benefits, as well as risks associated with organisms that fall into the gray area.

The consistency between these documents was hard won, but highly worthwhile. To counteract any continuing uncertainty, NISC should actively and clearly reaffirm that actions to manage invasives will focus only on those alien species that cause or are likely to cause economic or environmental harm, or harm to human health. NISC agencies should also ensure that this information is widely disseminated to all relevant field personnel.

In conclusion, the challenges posed by invasive species are already daunting. Eliminating the vagueness associated with the issue’s terminology will contribute greatly to developing new policies and management strategies to protect the economy, environment, and public health of the United States.

# Demystifying Milfoil

By

Scott Williams and Roberta Hill

Volunteer Lake Monitoring Program, Center for Invasive Aquatic Plants

Almost everyone has now heard of milfoil, that nasty invasive plant that threatens to ruin Maine's lakes, but there seems to be some confusion. How many types of milfoil are there? Is milfoil native to Maine? If not, how long has it been here? If so, why are we so worried about it? Is milfoil the only aquatic plant that threatens Maine's lakes? Much of the confusion may come from the way the term "milfoil" has been used in recent years.

"Milfoil" has been used as a catchword to get the message out about the threat of invasive aquatic plants in Maine. There are the "Maine Milfoil Summits," the "Milfoil Bill," and the formation of the "Maine Milfoil Coalition," etc. Having a word that people could easily identify with has been helpful in raising awareness. *But the practice of reducing a complex problem to a single generic term always has its down side. It fails to provide an accurate and complete picture. The term "milfoil," when used to describe the current threat of invasive aquatic plants to Maine's lakes, is limited and potentially misleading for a number of reasons.*

First, several milfoil species are native to Maine lakes. These plants are not harmful or threatening. In fact, like all of our native aquatic plants, they provide many benefits to the lake ecosystem. Native plants provide essential habitat for wildlife and protect water quality by taking up nutrients and protecting the shoreline from wave and wake action. Native aquatic plants are good for our lakes and ponds. *It would be most unfortunate if the public were to think that all members of the milfoil family were undesirable, and that they should be removed.*

Secondly, there are several non-milfoil plants that are just as likely to invade Maine's lakes in the coming years as the invasive milfoils. The current list of "Maine's most unwanted aquatic plants" (determined by the Maine Department of Environmental Protection (DEP), and included in the laws passed by the Maine Legislature in 2000 and 2001) includes the following eleven: Brazilian elodea, Curly leaf pondweed, European naiad, Fanwort, Frogbit, Hydrilla, Water chestnut, Yellow floating heart, Parrot feather, Variable-leaf milfoil and Eurasian watermilfoil. *Only the last three of these are actually milfoils. But all of these plants have been identified as imminent threats to Maine lakes. Indeed, hydrilla, considered by many experts to be one of the most aggressive and persistent invaders on the list, has now been found in two waterbodies Maine.*

Here is an example of how generic language can be confusing. A Sebago Lake website posts the following Sebago Lake "fact."

"Water plants native to the lake include pipewort, bur reed, water lobelia, spikerush, pondweeds, water celery, coontail, water milfoil."

Though the statement above is very likely accurate, in light of the recent attention focused on non-native invasive milfoils, the listing of "water milfoil," without further explanation, has caused some confusion, to say the least. Some have taken the statement to mean that the milfoil that has appeared in the tributaries and coves of Sebago Lake over the last twenty years, Variable watermilfoil (*M. heterophyllum*), is native to Sebago Lake and therefore nothing to worry about.

Variable watermilfoil is *not* native to Sebago, to Maine, or even to New England. According to biologist C. Barre Hellquist, coauthor of *Aquatic and Wetland Plants for Northeastern North America*, the plant migrated, by way of human activity, to New England from the south and west (e.g., Michigan and Oklahoma) some time in the 1940s.

According to Biologist David Cortemanch, Manager of the Environmental Assessment Division at the Maine DEP, variable watermilfoil (*M. heterophyllum*) was first identified in Sebago Lake in the late 70s, and it was likely present in the lake for a few decades before it was identified.

There are many species of watermilfoil (genus *Myriophyllum*) worldwide. The *National List of Plants Species that Occur in Wetlands* lists six milfoils that are native to Maine. This is why the website fact is likely accurate. It would not be surprising to find one or more of these native milfoils in Sebago Lake. Indeed, over the last few years, Volunteer Lake Monitoring Program's Center for Invasive Aquatic Plants (VLMP~CIAP), Portland Water District (PWD), and the DEP have received requests to identify many aquatic plant specimens that have turned out to be native milfoils.

So variable milfoil is not native to Maine. Yet, it has been here for years, and it *hasn't* taken over Sebago Lake. What's the fuss?

Here's the fuss: Variable watermilfoil, which grows to a maximum depth of ~12 feet, will never overtake a lake like Sebago that is dominated by deep water habitat (often exceeding 100 feet), but it can become a significant nuisance in coves and near shore areas, interfering with boating and swimming and causing property values to decline. Variable milfoil can take over shoreline areas previously inhabited by native plants and negatively impact an important habitat. This is, of course, true for other Maine lakes that are infested with Variable watermilfoil.

Having no baseline data to work with, it is impossible to know how fast the plant is spreading in the lake and how many new colonies are forming each year. The Portland Water District began mapping milfoil sightings on the lake in 2000 and is currently working to organize a comprehensive screening of the lake's shoreline. The VLMP "Invasive Plant Patrol" screening project, a volunteer training program that is open to the general public, will be implemented through public workshops on lakes throughout Maine during the next several years. Having baseline data is essential to determining an appropriate action plan for Sebago Lake, and an effective prevention and identification plan for other lakes throughout the state.

Sebago Lake is one of the most popular boating lakes in Maine and in New England. Given that boats are the primary ways these plants get from lake to lake, the invasive milfoil found in Sebago is a potential threat to every other lake in the region.

Make no mistake – the three species of milfoil listed as "unwanted" in Maine lakes are aggressive and invasive. Every effort should be taken to keep them out of Maine lakes. But other invasive species are also present in Maine and more are on the horizon.

A great slogan for this issue has been: "Spread the Word, Not the Plant." *We should make sure that the words we are "spreading" are clear and accurate.* Perhaps it is time to adopt more accurate terminology. When speaking about the issue (and not about a specific plant), the term "invasive aquatic plants" or "lake invaders" works better than "milfoil" in almost all cases. It may not form a nice alliteration with the name of our state, and lend itself to such catchy headlines as "Milfoil Makes Mess of Maine Lakes!" but give it time. It may grow on you.

Revised: 5/17/11

# INVASIVE SPECIES Q & A

With all the attention being paid to invasive plants like milfoil, people are asking a lot of questions. You can obtain additional information from the Dept. of Environmental Protection at 1-800-452-1942 or by visiting their website at [www.mainedep.com](http://www.mainedep.com), or by calling the Dept. of Inland Fisheries & Wildlife at 287-8000.

- **What are invasive species?**

Invasive species are plants, animals and even microbes that are introduced from other regions and aggressively out-compete native species.

- **How are invasive species spread?**

Invasive species are usually spread as a result of human activity. Examples include carp from illegal fish stocking, Eurasian water-milfoil from boat and gear transport, and zebra mussels from engine cooling water and live wells.

- **What harm do these critters do?**

It varies with each species. For example, invasive aquatic plants can grow densely, crowd out native plants, reduce fish movement and stunt growth. In dense beds, invasive aquatic plants can shade out the bottom, reduce the number of snails and other useful animals, and change water chemistry.

- **What's at stake?**

Every year in the United States, government agencies and private citizens spend over \$100 million to combat invasive aquatic plants. Closer to home, Vermont has spent over six million dollars since 1980 to control these plants, and in 2009 received over \$1,080,000 in requests from municipalities for help in dealing with the problem. In addition, invasive species cost billions of dollars in lost recreation and property values, and ruin habitat for native species.

- **Does Maine have a lot of invasive species?**

Right now, Maine has at least 45 invasive aquatic species, ranging from green crab in ocean waters to white carp in a number of rivers. There are literally scores of other invasive species that have spread into other New England states in the last few decades. Maine has documented at least sixteen lakes and nine rivers and streams with invasive variable leaf water-milfoil, two with a hybrid of variable leaf water-milfoil, two with Eurasian water-milfoil, two with hydrilla, two with curly leaf pondweed and one with European naiad. We know of at least six other aquatic invasive plants which are either in New England or likely to be here soon.

*Continued...*

- Aren't all plants good for fish like bass?

Plant life in lakes and streams is essential to good fisheries. In moderate densities, aquatic plants provide just the right blend of cover and edge for successful fish growth as well as places to produce forage for smaller fish. The very dense plant growth often seen with invasive species like milfoil and water chestnut has the opposite effect.

- What is Maine doing about the problem?

In 2000, Maine launched an effort to prevent the spread of invasive species, starting with aquatic plants, the most obvious problem. This includes educating people on how to recognize invasive aquatic plants, avoid spreading them, and what to do if they find them. The effort also includes thousands of voluntary boat inspections by wardens and volunteers, information given to incoming motorists, and projects to eradicate new infestations where possible. We are also cooperating with other states in our region along with federal agencies.

- Why bother to do all this if the plants are going to get here anyway?

We know from other states' experiences that we can slow down the spread (and even prevent introductions) in some instances. The longer we keep these pests out, the more time we have to develop better control methods and the more recreation people can enjoy without these species in their favorite lakes.

- When is a sticker required?

A Lake and River Protection Sticker is required to be posted on the bow of all motorized watercraft when operating on inland waters. This sticker requirement applies to both motorboats registered in Maine and motorboats from other states operating in Maine. For residents, the sticker has been combined with the registration sticker. No sticker is required for watercraft on tidal waters or for canoes and other boats not requiring registration. Contact your regional warden service headquarters for the exact boundary between tidal and inland waters on specific rivers.

- Where do I get the sticker?

The cost is \$10 for Maine registered boats (which is included in the watercraft registration fee), and \$20 for those registered in other states while operating on Maine's inland waters. New stickers must be purchased annually. Nonresidents can purchase stickers wherever boats are registered, fishing licenses are sold, and through the Inland Fisheries and Wildlife online store.

- What does this sticker pay for?

Of the funds raised, 100% go towards efforts to prevent spread of invasive aquatic species. None of this money will be used for other DIFW or DEP work. Along with new warden staff and DEP specialists, much of the money is going to volunteer work and education efforts along with the boat inspections.

# INVASIVE LAKE PLANTS: WHAT ARE THE COSTS?

Maine is the only New England state that has not experienced serious infestations of invasive aquatic plants. Unless real efforts are made to prevent these plants from finding their way into our lakes and ponds, we will have to pay the high cost that other states have faced, including:

## ***RECREATIONAL LOSSES: Heavy Plant Growth = Less Enjoyment for Everyone!***

- Entanglement of boats and motors in thick weed beds
- Problems for fishermen
  - Stunted growth of some species due to high plant densities
  - Difficulty navigating
  - Impact on fisheries resulting from plant control measures
- Reduced shore front property values on lakes that are infested
- Reduced tax and retail revenues to communities with affected lakes
- A nuisance and potential danger to swimmers
- Revenues from tourism may decline

## ***METHODS USED TO CONTROL AQUATIC PLANTS: Very Costly and Potentially Damaging to the Environment!***

- **Mechanical Plant Harvesting (cutting/mowing):** \$350-1500 per acre. Does not remove rooting systems and ensuing plant fragments could spread plant infestation. Ongoing maintenance generally requires two to three cuttings per season to obtain acceptable control.
- **Herbicide Application:** \$200-\$1000 per acre. Costs vary depending on treatment rate, chemical used and water depth. Generally needs to be repeated every two years. Negative effects include the loss of beneficial plants, nutrient release, water use restrictions, questions concerning long-term impacts to the ecosystem, and social acceptability.
- **Bottom Barriers:** \$25,000-50,000 per acre. Limited application due to cost, difficulty in stabilizing large areas, and impacts on the lake ecosystem.

## ***REAL DOLLAR COSTS TO OTHER STATES:***

- **VERMONT:** Since 1980, the state has spent over six million dollars in federal, state, and local funds to prevent and control the spread of invasive aquatic plants. The state currently spends \$200,000 annually just to staff invasive plant control programs for only 46 of its 285 larger lakes.
- **NEW HAMPSHIRE:** \$100,000 in state and local operating funds is used annually to support 7-9 invasive plant control projects. This amount does not even come close to the public demand for programs for New Hampshire's 55 infested lakes.
- **MASSACHUSETTS:** Massachusetts spends over \$290,000 annually on grants for local lake projects, most of which is used to battle invasives in its 298 infested lakes. For state properties alone, \$95,000 a year is spent on operations to control invasive aquatic plants.
- **CONNECTICUT:** More than \$150,000 a year in state funds is spent to cost share local projects for invasives control.
- Many states have had to hire full time coordinators just to manage invasive plant issues!

**Everyone Agrees on the Most Cost Effective Solution:  
PREVENTION, PREVENTION, PREVENTION!**

# Frightening Factoids

## About Aquatic Invaders

~ A tiny plant fragment, or a single seed carried on a boat or trailer can begin the infestation of an entire lake. Invasive species, unlike other forms of pollution, are self-sustaining.

~ An invasive plant population in a lake can double or triple in size every year.

~ Invasive plants are forever! There are very few documented cases of successful eradications.

~ Some of the control measures used to fight invasive aquatic plants are nearly as destructive to lakes as the plants themselves. Control measures may threaten rare or endangered species in a water body.

~ Lake associations and towns in other states have been battling Eurasian milfoil for decades! Approximately 8-10 million dollars in public money is spent fighting this plant every year.

~ Invasive aquatic plants can compete with and eliminate beneficial native aquatic plants.

~ The introduction of a single invasive species to a lake can virtually ruin recreational opportunities, alter fish and wildlife habitat, affect water quality and lower shoreline property values.

~ Recent research in Vermont shows that invasive plants can cost shore line landowners on infested lakes over \$12,000 each in lost property values!

~ Maine's neighboring states spend hundreds of thousands of dollars each year to prevent and control the spread of IAS.

~ All of the New England States, as well as 41 other states and six Canadian provinces are battling Eurasian milfoil, water chestnut, and a broad group of other invasive species.

~ A total of \$100 million is invested annually in the U.S. to control invasive aquatic plants.

~ Hydrilla can be even worse than Eurasian milfoil (EWM)! This aquatic invader can completely overtake a population of EWM! From \$20-30 million in public money is spent every year battling Hydrilla in the US.

~ Massachusetts spends over \$290,000 annually on grants for local lake projects, most of which is spent on battling invasives in their 298 infested lakes.

~ The US Coast Guard estimates that economic losses and control efforts cost the United States about \$5 billion each year.

~ Zebra mussels can clog water pipes so severely that city water supplies can be cut-off. This happened in 1989 in the town of Monroe, MI for three days.

**The most effective and inexpensive approach to the problem of invasive aquatic species is PREVENTION.**

# INVASIVE SPECIES AND THE ENVIRONMENTAL ETHIC

From a talk delivered at the 6<sup>th</sup> Annual Milfoil Summit, 2/25/05

by

Evan Richert, Associate Research Professor, Muskie School of Public Service, University of S. Maine

Adm. Horatio Nelson, the famous British naval commander, once wrote: “But in case signals can neither be seen or perfectly understood, no captain can do very wrong if he places his ship alongside that of the enemy.”

Not being a ship’s captain I don’t know exactly what that means, but whether in politics or government or business, I have taken this as a metaphor – a piece of good advice to get as close as possible to an enemy, or a problem, or a disagreement and learn about its character and what is driving it as best you can, so that you can try to take it to a satisfactory resolution. The advice seems good, in any case, when it comes to invasive species, some of which are clothed in great beauty and false hope, others of which slip in as hideaways, and a very high percentage of which arrive with the complicity, witting or unwitting, of human beings who did not take the time to get to know what they were dealing with. It is a good idea to take the measure of exotic species, to determine what kinds of problem they are, to determine which may or may not be enemies, and, though they may not be seen and may not be perfectly understood, take the necessary actions to prevent or contain the spread of those that earn the label, invasive.

Here is what I think we know about exotic species in the U.S. in general:

-- Approximately 4,000 species of exotic plants and 500 species of exotic animals have established free-living populations in the U.S. (Alien Plant Working Group, undated) Some were purposeful introductions, brought into their new habitats for economic reasons or for pleasure. Many others were accidental introductions.

-- Of these, nearly 700 are known to cause severe harm to agriculture, and more than 1,000 have been identified as a threat to native flora and fauna as a result of their aggressive characteristics, earning them the label of invasive.

-- This also means that 75% to 85% of exotics are not known to be invasive. Many have cautioned not to paint all exotics with the same brush; many have been incorporated into our gardens, our recreation, and our economy. But those that are invasive have wide-spread, damaging effects: reduced biodiversity, disruption of existing ecosystems, and impacts on the food supplies, recreation, and other resources of human communities.

Beyond these facts, in the interest of getting to know these species, it is useful to ask: is the problem of invasives primarily biological? Or is it primarily economic? And is there an ethical component to the problem—that is, if there were not a direct economic component to the problem, would we care? The answers frame both our public and private responses to invasives: how much we are willing to invest in solving the problem, how much we are willing to regulate ourselves, how much effort we are going to put into education.

## BIOLOGICAL

The problem obviously has a biological component, and knowledge of the biology of invasives is central to preventing their arrival, to their eradication if they do arrive, and to their containment if eradication is impossible.

Exotics that are invasive succeed in their invasion for inherent biological reasons. As noted in a recent issue of *Conservation Biology* (Allendorf and Lundquist, 2003), they may be intrinsically better competitors because they evolved in a more competitive environment. They may find themselves

relatively free of enemies, parasites and disease, which means that they end up with more resources and opportunities for growth and reproduction than native species that have co-evolved with a community of species, both cooperators and competitors. And they may gain biological advantage in another way. Native populations may have evolved adaptations for their particular habitats that give them advantage in extreme events, such as storms, drought, or fire that may come into play every 50 or 100 years. But these same advantages may carry a small price in efficiencies in the short term, which may be constraining when compared to an introduced species that has not been burdened by such adaptations. In these cases, the introduced species will pay in the long run, but may cause havoc in the short run.

If the problem of invasive species were only a biological issue, one could be neutral toward them, even admiring of them. We would battle them, because we, too, are biological beings that compete for space and habitat. But we would know that these species are doing what all species are designed to do – disperse, secure a position in a community that allows them to thrive, and from that position to reproduce and widen its territory as much as possible. Human beings could be particularly admiring, since we excel at these things ourselves. And we would understand that nature has a way of evening things out over the very long term: species come and go; ecological communities are structured and re-structured; and nature lives on.

## **ECONOMIC**

But for anyone who might, in some intellectual way, be admiring of the biological capabilities and achievements of successful invasives, the economic component of the problem dampens our enthusiasm immediately. This is a matter of self-interest, a direct harm or threat of a harm that moves us to action. The costs are documented to be high.

For example, Kevin Boyle, Steve Kahl, Roy Bouchard, and others have documented the importance of great ponds to Maine's economy and tax base; and, in turn, have quantified the impact of water clarity on the value of properties around lakes. For example, the loss of 1 meter of clarity in a great pond such as Thompson Lake or Pushaw Lake can cumulatively depress property values by \$6 million to \$10 million dollars. (Boyle et. al. 1998) And that does not account for the spin-off impacts on tourism and the outdoor recreation industries that rely on healthy lakes and marine systems.

Nationally each year, invasive plants cause economic losses and expenditures in farming, forestry, and rangelands measured in the billions of dollars. The Office of Technology Assessment estimates that invasive species of weeds cost crop and livestock production more than \$5 billion per year, plus the direct and indirect costs of using herbicides to try to control the weeds. The National Park Service and the Fish and Wildlife Service alone spend an estimated \$12 million per year to control exotic plants.

And all of this apparently is just a fraction of total costs. When everything is accounted for, from lost production, to environmental costs, to the costs of containment, to the costs of anti-fouling measures in utility lines, writers in the journal *BioScience* in 2000 estimated the total cost of invasive species in the U.S. at an eye-popping \$125 billion per year.

This, certainly, is what brings all of you here. According to an examination of the role of great ponds in Maine's economy, conducted for the Great Ponds Task Force in 1997, the economic activity associated with lakes and ponds leads to \$1.2 billion in annual income for Maine residents and 50,000 jobs. (Boyle et. al., 1997) The economic consequences of milfoil and other invasives in Maine's lakes and ponds are too great to ignore.

## **ETHICAL**

But is there also an ethical component? If so, our reaction takes on a different dimension. By definition, an ethical component requires us to act *contrary* to economic self-interest – to take action, or to

refuse an opportunity, out of concern about something bigger than we, or out of obligation to a community or a generation that is not ours.

The ethical component of invasives has at least two parts to it. The first is only partly ethical; arguably it is really another aspect of the economic problem, because it has to do with who pays. The question is whether those who cause the problem appropriately bear the cost of solving it. We know that, while species invasions are a natural biological event, the rate of their occurrence and the distances traversed by species now exceed by orders of magnitude the invasions of a few hundred years ago. They are directly the result of human movement and trade. Some, like carp and European starlings, have been introduced on purpose. But far more often, they are introduced accidentally—such as Eurasian water milfoil by recreational boaters and anglers and zebra mussels via ballast water. Did you know that it is estimated that between 3,000 and 10,000 species of protists, animals, and plants are in motion around the world on any given day, in the ballast of ocean-going ships? The Japanese shore crab, now colonizing Atlantic North America, is one of them.

This is a question of fair distribution of costs and benefits, and that is why it is at least partly an ethical question. Those who have been responsible for inadvertently introducing species into new habitats may not have been willing to make the investment to prevent such accidents from occurring. They may not have realized the dangers, and in any case the dangers would be unlikely to have much economic impact on their own welfare. Rather, the costs of such accidents are borne by people other than those who have catalyzed the accidents. As Jeffrey McNeely, Chief Scientist of The World Conservation Union, has pointed out, the costs are in this way externalized. (Undated)

There is also a more purely ethical component to the invasives problem. The raw, ethical question is this: would we care about invasives if it were not for the direct economic harm to property values, to livelihoods, and to the enjoyment of resources we regard as placed on earth for our use? For that matter, *should* we care?

The non-economic problem associated with invasives is the homogenization of nature: taking a complex, resilient ecosystem that has evolved over thousands of years and simplifying and homogenizing and weakening it. As species invasions have accelerated in numbers and space well beyond background levels, ecosystems are less and less able to absorb their impacts. As a result, they are another manifestation of homogenization that comes with human colonization of local, regional, and global ecosystems. A recent article in the respected journal *Conservation Biology* asserts that the impact of invasive events on biodiversity is widespread – that invasive species are at least partially responsible for the extinction or imperiled status of 49% of the extinct or imperiled species in the United States. (Lodge & Shradler-Frechette, 2003)

If there were no economic consequences to this, I wonder if we would care. A little more than 30 years ago the U.S. passed the first federal statute, the Endangered Species Act, to grant de facto existence rights to species of plants and animals. In concept, at least, the Act recognizes existence rights of other species apart from their potential value as instrumentalities of human beings.

Yet, there is a great deal of evidence that our ethical values—that is, our willingness to act contrary to economic self-interest for a purpose greater than ourselves—do not extend to the homogenization of nature. The best evidence arises from the way in which we have chosen to spread ourselves across the landscape over the last half-century. Sprawl, as this pattern of settlement has become known, is one of the great homogenizers of nature. Even at low densities of one unit per 5 to 10 acres, sprawl reduces or eliminates the interior habitats required for biodiversity. The diversity of life quickly halves, and halves again, as large blocks of open space are reduced to 1,000-acres, 500-acres, and 50-acres, or are punctuated with house lots on 2, 5, or 10 acres. Yet, this is precisely what most suburban zoning ordinances now require.

Suburban sprawl, so far, has been impervious to ethical arguments dealing with pollution of the commons, reduction of wildlife habitat, and the homogenization of nature. Economic arguments simply trump ethical arguments. As a result, those of us who are trying to slow down or reverse sprawl must resort to economic arguments of our own. There are plenty – including tax burdens, loss of the competitive advantage that is our quality of life, inordinate transportation costs, and so forth. And right now, the statewide organization GrowSmart Maine, led by its president Alan Caron, is launching a major analysis of the relationship between sprawl and Maine’s economy—an analysis that we believe will definitively link the need to defuse sprawl to the future economic well-being of the state.

But the point is that, when it comes to common resources, like wildlife, the air, the great ponds, and so forth, we must rely on economic rather than ethical considerations if we are to protect them.

This is not exactly what Aldo Leopold had in mind, when he wrote in *A Sand County Almanac*: “Examine each question in terms of what is ethically and aesthetically right, as well as economically expedient. A thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community. It is wrong when it tends otherwise.”

Fortunately or unfortunately, we need not rely on the ethical component to stir interest in invasives. The economic imperatives are strong enough to engage public policy, and, thanks to your efforts, public awareness of the problem is growing. The volunteer efforts and the public service mounted by the people in this room, and many others, around the control of milfoil and other lake invasives are remarkable. And, economically driven or not, it is a testament to Mainers’ feelings for nature.

Let me conclude by saying that when I hear or read about invasives, a little poem by Ogden Nash comes to mind. It is about one of the most prolific introduced species in North America, the Rock Dove (now officially known as the common pigeon):

“Toward a better world I contribute my modest smidgin;  
I eat the squab, lest it become a pigeon.” – Ogden Nash

# MDEP's prevention and control efforts

Following are brief descriptions of program elements with major budgeted expenses for calendar year 2011. Budgeted salary and fringe for 3 DEP staff positions totals \$256,073 in 2011. Percentages in the above chart include an estimate of staff time spent on each program element; see text below for detail. Please email [milfoil@maine.gov](mailto:milfoil@maine.gov) with questions regarding DEP funding and budget.

Note: The Program pays approximately 15% in indirect cost on every dollar spent except for grant funds. Budgeted indirect cost for 2011 calendar year is \$58,355.

## Monitoring

Support from the Maine Lake and River Protection Sticker permits the Voluntary Lake Monitoring Program's Center for Invasive Aquatic Plants to add more trained volunteers to its existing cadre of 2,300 volunteers able to identify invasive plants statewide. These "citizen scientists" provide a core force for surveying boat ramps, inlets, dock and swimming areas, and other areas potential plant invasion. Expenses include approximately \$32,650 for Invasive Plant Patrol Workshops, \$47,750 for technical assistance and public outreach, and an estimated 15% of DEP's Invasive Aquatic Species Program (IASP) staff time.

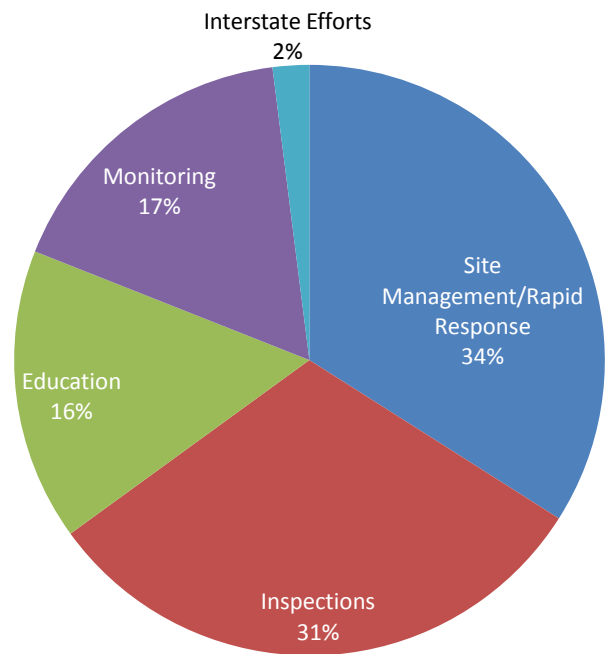

## Education

The Maine Lake and River Protection Sticker supports educational activities necessary to both inform residents and visitors of the invasive species threat as well as promote behaviors that prevent the spread of new infestations. Those activities include

- Public speaking opportunities
- Production and distribution of brochures
- Outreach to plant retailers and schools that use plants as classroom tools
- Warning signs on infested and non-infested lakes and ponds
- Paid print advertising, and
- Opportunities in print, television, radio and at outdoor sports trade shows to spread the word on not spreading invasive plants.

## DEP Invasive Aquatic Species Program

2011 Calendar Year Budget Breakdown

Approximately \$13,300 is budgeted for myriad education and outreach efforts plus an estimated 32% of IASP staff time.

## Boat Inspections

One day all boaters will inspect their watercraft and trailers for hitchhiking plants and other biological debris that potentially migrate from lake to lake. Until then, a boat inspection is the most effective way to assure biological threats do not spread and, at the same time, provides an opportunity to show boaters the importance of taking the time to inspect and remove plants and other organisms. Trained boat inspections conducted by lake associations and municipalities are sponsored by the Maine Lake and River Protection Sticker and have increased from 2,500 in 2001 to over 70,000 in 2010. The 2011 Courtesy Boat Inspection Program budget includes \$95,000 for small grants to local boat inspection programs, \$75,960 for inspections to prevent spread from infested lakes, \$33,870 for volunteer training, grant administration, and project work, and an estimated 20% of IASP staff time.

# MDEP program

*Continued from Page 4*

## Plant Management and Rapid Response

If an invasive aquatic species is detected in a Maine water body, Maine Lake and River Protection Sticker revenues go to work to limit its spread both within the infested lake and beyond. Efforts include manual removal of plants by trained volunteers and professional SCUBA divers, deployment of warning buoys to direct boat traffic away from infested areas, and—in worst-case situations—the application of herbicides.

The 2011 budget includes approximately \$54,000 for IASP management of existing infestations, including hydrilla (Pickerel Pond and Damariscotta Lake) and Eurasian water milfoil (Salmon Lake), and rapid response to new infestations. Also included is \$70,000 for grants to local plant removal programs, \$7,000 in grant administration, and an estimated 28% of IASP staff time.

## Task Force/Interstate efforts

Collaboration, both with neighboring states which deal with older, more extensive invasive plant problems and with stakeholders within Maine, is essential if efficiencies and priorities are to be set. Not only do nearby

*Courtesy of Jim Evans/Waterville Morning Sentinel*

**John McPhedran of the Maine Department of Environmental Protection finds a fragment of Eurasian milfoil while setting up a net on Salmon Lake in North Belgrade.**

states have a greater variety of invasive species able to migrate into Maine, they also have more experience in curbing or controlling plant infestations. Communication and the free exchange of experience are essential.

Within Maine, a Governor-appointed panel of stakeholders, the Interagency Task Force on Invasive Aquatic Plants and Nuisance Species, overviews and advises how the Maine Lake and River Protection Sticker revenues serve the state best. As with officials in neighboring states, rapport is key. The 2011 budget includes an estimated 2% of IASP staff time for task force and interstate efforts.

## Milfoil Sticker Sales and Revenue as of January 25, 2011

Calendar Year	Resident	Amount	Non-resident	Amount	Grand Total	IF&W Share	DEP Share
2002	100,049	\$900,441.00	9,814	\$186,466.00	\$1,086,907.00	\$434,762.80	\$652,144.20

# MDIFW's invasive species program

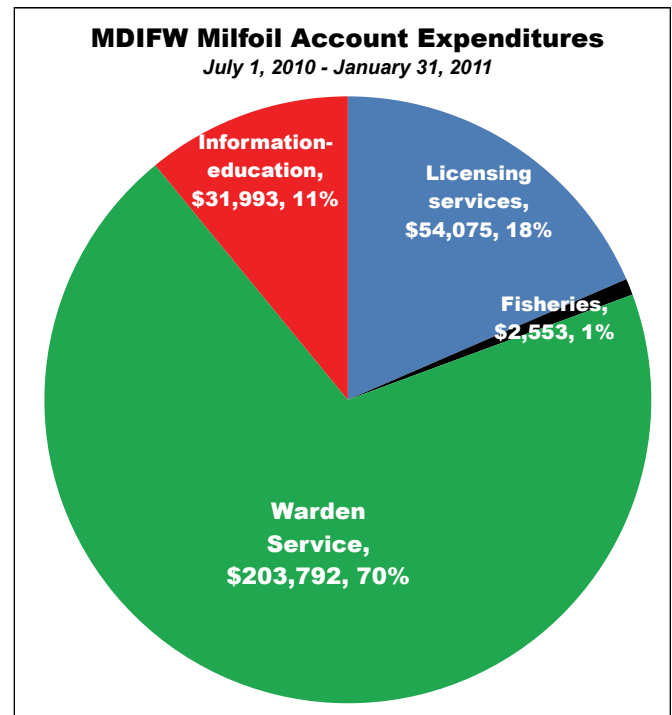

Wardens checked 13,856 boats in 2010. Wardens issued 128 summonses and 312 warnings for failure to produce a valid registration and Lake and River Protection sticker. Since 2004 wardens have issued 6,639 summonses for this violation. Again this year with our outdoor partner program we attended about the same number of shows, right around 70 public events. Safety Officer Mike Sawyer again reported that his staff taught about 10,000 students again and provided invasive species information to all students.

Corporal John MacDonald worked with three interns this year with a focus on boater education. Corporal MacDonald reported that he and his staff responded to 36 different calls for service where they interacted with members of the boating community with our outdoor partners program. The intern's focus was on milfoil education as well as boater education and boating safety practices. The three interns spent many hours at boat ramps located in the southern part of the State talking to boaters about these topics..

Illegal fish introductions are putting Maine's valuable native fisheries at risk. DIFW's Fishery Division is busy confirming the presence of illegally stocked fish such as northern pike, smallmouth bass, black crappie, minnows and other species into a number of Maine lakes.

Below are just some of the projects from 2010.

- DIFW Fisheries Division completed the reclamation of Big Reed Pond during the fall 2010. This is the largest and most logistically challenging work activity in the division's history. The reintroduction of native Arctic charr and brook trout will start occurring in 2011.
- Biologists and wardens in conjunction with Limestone Police successful removed an illegally stocked pacu (South American fish species) from a water in Limestone in August 2010. The person responsible for releasing the pacu into the wild was charged and successfully prosecuted.
- A number of goldfish ponds were chemically reclaimed in 2010.
- Conducted assessment and removal activities focused on the illegal introduction of walleye in the Belgrade Lakes (Great and Long Ponds). These activities will continue in 2011.
- DIFW Fisheries Division redeveloped the pond reclamation program to meet the standards of the new General Permit. Several staff members have been licensed to apply aquatic pesticides, and new equipment has been purchased to allow safer and more efficient applications. This will allow the Fisheries Division to mitigate long-term invasive fish problems, and deal with rapid responses to exotic introductions.
- Boat electrofishing to follow-up on report of largemouth bass in Hebron Lake (Monson) and associated rapid response forms.
- Investigation of rainbow smelt (illegal introduction) spawning runs and sampling of charr population in Wadleigh Pond (T8R15 WELS).
- Monitor/assess/suppress Northern pike in Pushaw Lake (Hudson, Old Town, Orono, Glenburn). Outreach to Pushaw Lake Snowmobile Club and local anglers and property owners. Spring trapnetting in known spawning area to remove adult northern pike.
- Piscataquis River Pike Risk Assessment Committee – Determine risk of pike to resident fish populations above the Howland Dam when the natural bypass is constructed (free swim for all fish species).
- Radio telemetry of tagged Northern pike in Pushaw Lake to determine behavioral patterns and identify spawning areas to facilitate effective removal efforts.

## WHAT CAN WE DO TO PREVENT INVASIVE PLANTS?

Here are some things that can be done locally to prevent the introduction and spread of invasive aquatic species, in particular exotic plants. There are also a few notes about what cannot or should not be done.

The first thing to understand is that the threat of invasive aquatic species is not going to go away at any time in the foreseeable future. As long as people travel from one waterbody to another, the potential for the spread of unwanted aquatic organisms will persist. For any prevention effort to be effective it must be sustainable “over the long haul.” It is important, therefore, to choose the strategies that are most suited to the particular circumstances and needs of your community, and that can be adapted over time. The best way to do this is to organize a committee, with members representing a broad spectrum of community interests, to collect information and develop a comprehensive plan for addressing the invasives issue locally.

Many of the most effective strategies are very simple and inexpensive. Others will require more time, effort and funding. Volunteers can do much of the work, but there may be instances when the assistance of professionals may be warranted. For each project, there should be a designated individual who takes on the job of monitoring things over time, e.g., checking periodically that signs are still up, brochures are still being given out, etc.

### **1. Make sure that all public launch ramps have warning signs**

Use the signs developed by the VLMP and the DEP or make your own. Whichever you choose, remember that visual clutter can be an issue. Think about placement to increase the likelihood that boaters will actually see the signs. When placing signs, make sure to identify who owns the ramp and talk with them about sign placement etc.

Kiosks at landings are a good way to offer more information, but again, the best information is not useful if it is not seen. Sometimes the shorter, simpler, and more attention-getting the message is, the more effect it has. Be sure to avoid alarmist rhetoric – that turns many people off.

### **2. Post informational posters and flyers**

Look for key areas in your community where boaters (especially those from away) are likely to see public notices, such as community bulletin boards, local stores, sportsmen’s clubs, etc. Post the VLMP flyer material, both sides of the color brochure, or develop your own posters and flyers. The use of color and keeping the message simple increases the chances that the information will be read. (Electronic files of the VLMP brochure graphics are available upon request. Also, please feel free to take illustrations off our website.)

### **3. Ask your town office to hand out brochures**

Contact your town office and ask if they will hand out brochures (your own brochure and/or those developed by the DEP, VLMP or others) whenever boat and boat trailers are registered and when fishing licenses or the new “Protect Maine Waters” boat stickers are purchased. Non-resident fishing licenses and the boat stickers are also sold through local stores and agents, so they should be contacted as well.

Be sure to ask stores, tourist information locations, town offices etc. to put up posters (in effective locations) and stock brochures.

#### **4. Distribute flyers and/or brochures at ramps**

- a) Organize volunteers to stop by public boat ramps a few times each day and place flyers on vehicles with trailers. To reduce the chances of “reflyering” frequent ramp users, keep records of which vehicles have been “flyered” and avoid repeats when possible.
- b) Put flyers in a box at the ramp for people to pick up.

One problem with both of the above mentioned methods of distributing flyers is the potential for litter, so be prepared to pick up a few flyers from time to time. As with placing signs, it’s good to discuss the project with the ramp owner before hand.

#### **5. Create a portable display of posters, signs and brochures**

A portable display can be a terrific way to reach a wide audience. Move the display around the community – place it in schools and libraries, or set it up at public meetings and events, etc.

#### **6. Inventory all places where boats are launched and contact the owners**

Keep a list of who has ramps likely to be used by boats from other lakes, including the contact person and when last contacted. It’s good to renew these contacts in May and July each year.

- a) Private ramps open to others (such as marinas and sporting camps): When someone launches at a commercial facility, the staff there can use the opportunity to hand out brochures and may be willing to check boat trailers for plants. If you get this kind of cooperation, please make sure to acknowledge the owner and staff in your newsletter or newspaper article. The owner can also post a sign/poster for you.
- b) Other private ramps: Alert owners to potential problems. If they have guests use their boat launch, ask them to check the boat before launching.

#### **7. Boat inspection at ramps**

Having boat inspectors at ramps is perhaps the single most effective way to prevent the spread of invasive plants. It is imperative that the owner of the ramp (IF&W, DOC, Town, Sporting Club, etc.) knows and agrees with what you are doing. Above all, avoid conflicts with boaters by observing a few simple rules:

- a) Boater participation in your inspections is completely voluntary. View it as an opportunity to educate them. If they object to an inspection, or are “too busy”, simply offer them a brochure.
- b) Try to talk with boaters before launch; preferably while they are preparing their boat, and not while it is on the ramp if the facility is busy.
- c) Keep your message short. Boaters are often impatient to be off, and they will be more receptive to a few sentences (and maybe let you quickly show them the inspection process) if you are brief.

d) Never “expect” boaters to accept your message. Some people are very sensitive to implications that they should do things differently. If they are resistant or show signs of wanting to argue, it is best to thank them for their time and let them continue on their way.

You may want a mixture of volunteer help and paid interns, depending on your resources and the amount of time you think you can arrange for coverage at the landing. Obviously, you want to cover the highest use times -- weekends, vacation times (Memorial Day, July 4<sup>th</sup>), fishing tournaments, etc.

Lakes Environmental Association (LEA) offers boat inspection training for volunteer groups. Please contact LEA at 207-647-8580 or [lakes@megalink.net](mailto:lakes@megalink.net) for more information.

## **8. Boat Washing Stations**

Boat washing stations can be effective, but are generally quite costly to set up and operate. They may not be much more effective than careful inspections at preventing plant infestations. However, zebra mussels may be transported in engine cooling water and any container with lake water from another area. If an engine has not been flushed out with clean water before launching, at least run it “dry” for a few seconds so most of the cooling water will be expelled, preferably away from the ramp so it soaks into the ground. A few seconds should do it, and will not overheat the engine. Some boat owners will not agree to that. A better alternative would be to have a “boot” and clean water source for flushing the cooling system completely.

## **9. Incentives to cooperate**

Getting people to cooperate can be helped if something useful comes along with the education (key chain, water bottle, etc.). This can also carry your message: association logo or whatever take-home message you want.

## **10. Survey the ramp area and other likely sites for invasive plants**

The VLMP offers Invasive Plant Patrol training to help volunteers in your community conduct invasive plant surveys of lakes, ponds or streams. Please contact the VLMP for upcoming workshop dates and locations.

## **11. Using local media to put out the word**

Many areas have free advertisers or seasonal papers that will print short articles if you provide the information and especially a selection of clear pictures or graphics. The papers are often looking for content, and reviewing a few past issues will give you an idea for length, style etc. of what they may print.

The message might vary depending on the time of year and the project you choose. While you want to avoid sensational statements, your story should be presented in a way that will be of interest to the public. Any time you can put your issue in a local perspective, especially how the issue affects people, it makes for a better read. Some of these papers will print articles for you several times a year, particularly if you offer something a bit different each time. Media exposure works best if the message is short, positive and repeated in different ways.

Explore other outlets such as newsletters from organizations (besides lake associations) that make regular mailings and may be receptive to including your information. These can include local service groups, churches or clubs.

***Some other things you should know:***

State law, or other considerations may limit what can or should be done in some instances.

**Restricting Public Access:** Unless the Town or private club etc. owns a launch ramp and has the right to close it, it will not be possible to close the lake to boats and gear coming “from away”. Campaigns to do this can cause bad feelings among local people who rely on these access points to use lakes.

**Restricting Surface Use** (such as allowing only non-motorized craft): Only IF&W can set restrictions on surface use, such as maximum horsepower and the like, and they are limited by law as to what they can limit (horsepower size, use by personal watercraft) and for what reasons (public safety). There is a process to restrict surface use by petition for these reasons, but limitations apply to everyone using the lake (including camp owners). In the case of restricting personal watercraft, it also requires municipalities involved to agree to identical standards. For more information, call IF&W at 207-287-8000 or see their website at <http://janus.state.me.us/ifw/rv/boatlaws2000.htm>.

**Use of Herbicides:** Except in private ponds with no outlets, herbicide application to water requires a discharge permit from the DEP and in many cases, application by a licensed pesticide applicator. Pesticides themselves and professional applicators are regulated by the Department of Agriculture, Pesticides Control Board. For more information, please call 207-287-2731 or check the web at [www.state.me.us/agriculture/pesticides/homepage.htm](http://www.state.me.us/agriculture/pesticides/homepage.htm))

**Discharge licenses for pesticides to lakes are not allowed by DEP:** Under current law, DEP can apply herbicides for the sole purpose of restoring a water body. Repeated applications or the use of herbicides to simply suppress or manage, but not eliminate a plant population is not allowed.

There is growing anecdotal evidence that property owners are buying herbicides from local suppliers, through the mail, or over the Internet and using them illegally in lakes. Herbicides have been used on native populations of plants to eliminate them in front of camps. People may have the misimpression that because the chemicals are EPA registered, they are safe and benign. The suppliers rarely tell a person that applying them without proper permission is a serious legal offense and is hazardous to the environment (and to themselves if not done properly).

**Physical Control Methods:** Methods such as dredging, bottom barriers and weed harvesting require an “NRPA” permit. DEP can apply control methods without getting a permit provided it is for the *immediate eradication* of an infestation. If such physical control methods are to be done by parties other than the DEP or for management/suppression (without the prospect of eradication) then a regular NRPA permit is required.

Homeowners are allowed to *hand-remove* a swath of vegetation 10 feet wide perpendicular from their shoreline out into the lake. This will allow a place to swim and passage for boats. To do this, an owner needs to get a “Permit by Rule” from the DEP. Although a quick and simple process, PBR carries clear standards, which must be met. For information on NRPA and PBR standards, call a DEP agent at 207-287-3901 or 1-800-452-1942 or visit the web: <http://janus.state.me.us/dep/blwq/docstand/nrpapage.htm>

# Local Efforts Prevent the Spread of Invasive Aquatic Plants

Roberta Hill *Maine VLMP ~ Center for Invasive Aquatic Plants*

In response to the threat to Maine lakes, ponds and streams posed by invasive aquatic plants, many Maine communities have established “Courtesy Boat Inspection” programs. If you launched a boat into Maine waters this summer, you may have encountered this voluntary public education program in action. Inspectors are trained to examine boats, trailers and other gear for hitchhiking plant fragments, to educate boaters about the invasives threat, and to encourage lake users to adopt the “check-your-boat-every-time-you-float” habit. Over the past four years, there have been a number of confirmed cases of potential invasions being successfully averted by vigilant inspectors. In all cases, the fragments intercepted were plants officially listed on Maine’s watch list as imminent threats to Maine waters, all capable of taking root once introduced. In each case, the seized plant fragments were sent to the VLMP Center for Invasive Aquatic Plants where their identities were confirmed.

In July 2004, a sprig of curly leaf pondweed was caught by the wary eyes of Mark Dixon, a paid inspector contracted by the Raymond Waterways Protective Association to greet boaters at the Raymond boat launch on Sebago Lake. The personal watercraft carrying the fragment had last been launched in Candlewood Lake in Connecticut, a lake with known infestations. The owner, though thoroughly cooperative, assured Mr. Dixon that the gear was clean, as it had been recently washed at a high-pressure washing facility. Mindful that there is no substitute for a careful visual inspection, Mr. Dixon conducted a thorough inspection anyway, quickly finding the inconspicuous, yet potentially disastrous, fragment.

Curly-leaf pondweed (*Potamogeton crispus*) is an invasive aquatic plant, not native to Maine, that once established can form thick surface mats that interfere with recreation. Like all of the invasive aquatic plants on Maine’s watch list, curly-leaf also poses serious threats to lake ecosystems and local economies. Native to Europe, curly-leaf was considered the most severe nuisance aquatic plant in the Midwest until Eurasian watermilfoil appeared. It was accidentally introduced along with the common carp some time in the mid 1800s, and is now present throughout much of the US. The first rooted infestation of curly-leaf pondweed in Maine was confirmed in West Pond in the town of Parsonsfield in 2004.

Another close call occurred just a week or so later, when several stems of European naiad, again headed into Sebago Lake, were snagged by an inspector hired by the Portland Water District to monitor the Standish boat launch. The boat had a New York registration, but the “waterbody of origin” is unknown.

European naiad (*Najas minor*), also known as spiny-leaf naiad, can easily reproduce by fragmentation during the growing season. However, unlike most aquatic plants, European naiad is a true annual, relying upon seed production to return the following year. Prolific seed bearers, well-established populations may produce millions of seeds per acre. Once a healthy seed bank is established, European naiad is virtually impossible to eradicate. There are no known occurrences of European naiad in Maine.

***Portland Water District Courtesy Boat Inspector instructs a boater at the Standish boat launch on Sebago Lake***

On September 3, Lea Ramirez of Waterville was performing her routine duties as Volunteer Courtesy Boat Inspector on Great Pond in Belgrade when a boat from Rhode Island arrived at the launch. The boat did not have the required Lake and River Protection Sticker and Ms. Ramirez was quick to find a tangled mass of dried plant material dangling from the boat trailer. The visiting anglers, who generally fish in Chapman

Pond, Rhode Island, had never heard of milfoil or invasive plants, and when asked if there were lots of weeds in Chapman Pond, answered "yes, that's why we fish there!" Ms. Ramirez removed all visible plant material and the boaters, now seemingly "more concerned," cooperatively headed off to purchase a sticker. That was the last Ramirez saw of them. Ramirez bagged the plants and, following standard procedure, brought them into the CBI program coordinators at the Belgrade Regional Conservation Alliance.

***This fragment of Eurasian water-milfoil was removed from a boat entering Great Pond by Lea Ramirez, a volunteer CBI.***

Mike Little, Director of BRCA, though somewhat startled to see it, was quite sure he knew what they had. He sent samples to the VLMP Center for Invasive Aquatic Plants, where his suspicions were confirmed: the plants Ms. Ramirez had snagged were definitely Eurasian water milfoil (*Myriophyllum spicatum*), widely considered to be the most aggressive member of invasive milfoils. There are three milfoils on Maine's watch list. Two, variable leaf milfoil and Eurasian milfoil, are known to be established in Maine waters.

Testimony to the indestructible nature of this particular invader, the dried, completely dead-looking plant fragments removed from the Rhode Island boat were placed in water just to see if there was any chance they were still viable. The test was first conducted at BRCA, and then repeated at the VLMP. In both experiments, once back in water, the plants quickly rebounded, and in a few days time were "looking quite green and perky."

In 2005 another big snag occurred on Unity Pond. The Waldo County Bass Masters would be converging at the Kanololus landing on Sunday morning for their Father's Day Tournament. Harry Waters, the Courtesy Boat Inspector and boat launch/swimming beach attendant at the landing, and Dr. David Potter, professor of ecology at Unity College, teamed up to provide the necessary coverage. Dave arrived at the boat landing at 4:30 AM and awaited the first boaters of the day. That first boat arrived at 4:55 AM and it was not long before the landing area was teeming with vehicles towing slick-hulled boats and a host of eager anglers. Dave quickly understood the challenge: to inspect each rig with as great a speed as care would allow, while keep things moving at all times. Things proceeded like clockwork.

A careful observer by training and nature, Dave noticed during his inspection of the third boat of the morning that bits of debris were caught in the carpet-like fabric on the slider bunks supporting the hull of the boat. After that, he began to crawl on his hands and knees around and under every rig. Suddenly his well-trained eye found its mark. Stuck in the under side of one bunk was the spiny fruit of water chestnut, a notorious floating leaved plant that is prevalent in New Hampshire and Vermont, but not yet known to occur in Maine. Dave confiscated the water chestnut fruit, and showed it to the boat owner. Locating no other evidence of invasive plants, he allowed the boat to launch. Then, just to make sure nothing had been hiding between the boat and the sliders, inspected the trailer once again.

Not one to pass up a "teachable moment," Dave made an announcement of the snag to tournament entrants. "The fruit was viewed by most of the boaters and was handled and passed around by so many hands that the spiny tips of the four sharp claw-like projections on the fruit were completely worn away. If there were any remaining skeptics in the group, it is likely that even they walked away with a new appreciation for courtesy boat inspections, and would have to acknowledge that the statewide invasive plant patrol program and the boat sticker program serve a very valuable purpose indeed." And in the eyes of those who love Unity Pond, it was surely Dave who had made the "catch of the day."

In late July, a fragment of Eurasian water-milfoil was removed from a boat entering Sebago Lake at the Raymond Beach boat launch, by CBI and Raymond Waterways Protective Association Lakes Protection Ranger, Christina Perry. The fragment was found stuck between the boat and the carpeted trailer slide, about midway between the bow and the steering wheel. The boat was from New Jersey; the boater, a B.A.S.S. member, apparently visited numerous lakes across New England, criss-crossing state borders in pursuit of his sport. The last waterbody visited (one week before coming to Sebago) was Candlewood Lake in Connecticut, a lake well known to be infested with Eurasian water-milfoil. The boater, very supportive of Maine's efforts and the Courtesy Boat Inspection program, had inspected his gear shortly before it was re-inspected by Christina. He had not noticed the menacing hitchhiker.

**Dr. David Potter, volunteer Plant Patroller and Courtesy Boat Inspector, pulled an invasive water chestnut fruit off the trailer of a boat about to enter Unity Pond.**

In August, Bill Hart was on duty as a Courtesy Boat Inspector at the Town Dock on Rangeley Lake. A boat and trailer entered the dock from Massachusetts. The boater had his milfoil sticker on his boat and informed Bill that his boat was last launched in Lake Shirley in Massachusetts. According to Bill, “The gentleman was very supportive of the milfoil sticker and the effort to keep milfoil out of Maine lakes.” The boater assured Bill that he had cleaned his boat and trailer with a hose before traveling to Rangeley Lake.

As Bill inspected the boat and trailer, he spotted a plant fragment hanging from the trailer. When Bill held the plant up for the visitor to see, he was told that the plant was nothing to worry about, probably just a “grass cutting.” Suspecting otherwise, Bill bagged up the specimen for later examination, and proceeded with his inspection. Not finding any additional plant fragments, the boat was allowed to launch. But that was not the end of it. After the boat left the dock, Bill returned to the trailer for one last inspection. He noticed a small bit of green poking out of one of the holes on the inside of the steel trailer. Using care and persistence, Bill finally extracted the rig's well-concealed cargo: a healthy-looking stem fragment, about 14 inches long. Suspecting milfoil, Bill added the fragment to the specimen bag. Bill's suspicions were confirmed later that day by VLMP. The Massachusetts “grass clippings” were indeed Eurasian water-milfoil.

And these just name a few of the catches that have occurred. Every year more watchful folks catch potential new invaders. There is no question that the CBI program is working! With over 6000 lakes and ponds and thousands of miles of stream habitat, local groups and concerned volunteers play a very important role in the effort to prevent the spread of invasive aquatic plants in Maine. The Courtesy Boat Inspection program is coordinated by Lakes Environmental Association and Maine Congress of Lakes Association.

A “sister” initiative to the CBI program, creating a second line of defense against the threat of invasive aquatic plants, is the “Invasive Plant Patrol.” To date nearly 2000 volunteers have been trained by the VLMP Center for Invasive Aquatic Plants to survey Maine waters for the presence of invasive aquatic plants. The earlier an infestation is detected, the greater the hope for eradication. Almost all known infestations in Maine were first detected by alert and informed citizens. The Courtesy Boat Inspection program and the Invasive Plant Patrol program are both made possible with support of the Maine Department of Environmental Protection and boater participation in the Maine Lake and River Protection Sticker program. For more information on how you can get involved in this important effort please contact the VLMP Center for Invasive Aquatic Plants at 207-783-7733.

# Can Volunteers Make a Difference? You Bet!

## *Volunteer Early Detectors Help Local Authorities Nip New Infestation in the Bud*

The Great East Lake Improvement Association (GELIA) in Wakefield, New Hampshire and Acton, Maine has an active Weed Watcher program. (Weed Watchers is the New Hampshire corollary to Maine's Invasive Plant Patrol.) GEILA early detection program has grown steadily every year since its inception, and the association now has over 60 volunteer "watchers" on the lake, covering nearly all of Great East's eighteen miles of shoreline. On July 11, 2006 Great East Lake resident and volunteer weed watcher, Carol LaFond, was surveying her assigned sector near the public boat launch, on the Maine side of the lake, when she noticed a suspicious plant "standing out like a neon sign" among the native plants. She collected a specimen and brought it to local authorities. The plant was not in flower at the time and species identification was only possible through DNA analysis. (The flowering parts are needed to positively identify most milfoils.) DNA test results confirmed what had been suspected: the suspicious plant was variable water-milfoil (*Myriophyllum heterophyllum*). The response was swift and

carefully executed. Once the invasive plant and its roots were removed, Carol continued to revisit the plant removal site, as well as the surrounding cove area, on a weekly basis for the remainder of the open water season. No additional invasive plants were found. Additional surveys of Great East Lake beyond the cove seem to confirm that the introduced invader was detected and removed before it had a chance to become well-established or to spread to other areas of the lake. Having successfully averted what could have become an ecological and economic disaster for the lake and the region, GELIA has provided us with a compelling example of the enormous--and ultimately incalculable--value of volunteer early detection efforts.

## Strengthening the case for early detection: Eurasian water-milfoil in Salmon Lake

By Roberta Hill  
Program Director, VLMP's Center for Invasive Aquatic Plants

On August 4, 2008, Eurasian water-milfoil (*Myriophyllum spicatum*), one of Maine's "eleven most unwanted invasive aquatic plants" was confirmed to be present in Salmon Lake (also known as Ellis Lake) in Belgrade. Widely known as one of the most aggressive invasive aquatic plants in North America, Eurasian milfoil was previously known to occur in only one other Maine waterbody: Pleasant Hill Pond, a small quarry pond in Scarborough.

Unlike Pleasant Hill Pond, which has no public access, sees little if any recreational activity, and has limited connectivity to other Maine waters, Salmon Lake has an active public boat ramp, supports a wide range of recreational activities, and is a primary headwater to a major chain of lakes. But thankfully (for Salmon Lake and all of us) there is another big difference. The earlier infestation in Pleasant Hill Pond had almost entirely overtaken the available habitat in that waterbody by the time the infestation was detected. The infestation in Salmon Lake, by contrast, was detected relatively soon after introduction, before it became widespread in the waterbody. *It is this singular fact—the fact that the offending invader was detected early rather than late in the process of establishing itself in the waterbody, that tips the balance in favor of Salmon Lake.*

Early detection was of course not the only factor working to help assure a

The infestation of Eurasian water-milfoil in Salmon Lake (located near the public boat launch in an area known locally as Kozy Cove) was detected early and the response was swift and well executed, all of which bodes well for future efforts to control its spread.

favorable outcome for Salmon Lake. The entire course of events set in motion by the "early detector" Kurt Lakin—the vacationing Tennessee fisheries biologist who first noticed the suspicious plants—functioned like clockwork. Shortly after the suspicious plants were detected, specimens were collected and brought to the VLMP Center for Invasive Aquatic Plants for species confirmation. Within hours of documentation, the Departments of Environmental Protection (DEP) and Inland Fisheries and Wildlife (DIFW) began to mobilize their Rapid Response Plan. By August 5th, four days after the discovery of the infestation, DEP biologists had surveyed the site where the plants were first detected, and had determined that the infestation was sparsely distributed throughout a shallow cove, roughly seven acres in size. The area, known locally as "Kozy Cove," is between the public boat ramp off Route 8 and an outlet stream lead-

ing to Great Pond. Three days later, on August 8, a DEP dive team was dispatched to remove all visible plants. Simultaneously a team comprised of local residents, State agency personnel, trained Invasive Plant Patrollers, University of Maine Farmington faculty and students, and VLMP staff was organized and set to the task of surveying Salmon Lake and adjacent waters to determine if the plant had spread beyond the Kozy Cove area. As of this writing no additional infested areas have been found.

In addition to these actions, state officials have deployed buoys identifying plant sites, improved signage at the nearby boat ramp, communicated with lake shore residents on appropriate boat usage, and increased the hours of Courtesy Boat Inspections occurring at the boat ramp. Local residents and conservation groups have met to begin discussing strategies to guide future prevention, early detection, rapid response, management and monitoring efforts in light of the newly identified infestation. DEP divers have conducted three more "search and destroy" missions in the cove, removing any additional plants found (either undetected earlier, or newly sprouted; any tiny stem or root fragment left behind can quickly produce a new plant). A total of roughly one hundred stems have now been removed from Salmon Lake, and though new stems are found each time the divers look, there is good reason to believe that the

day will come in the not too distant future when no Eurasian milfoil plants are found. And the hope, of course, is that regular monitoring over time will provide Salmon Lake with a continued clean bill of health.

Nonetheless, the fact remains... had the infestation in Salmon Lake gone unnoticed for one, two or three years more, all the while spreading quietly within Salmon Lake and into adjacent waters, the efficacy of the subsequent "rapid response," no matter how swift and well executed, would have been significantly diminished. Like a serious illness or epidemic, the earlier an infestation is detected, the better the chances are for effective remediation.

In addition to providing a model of superbly executed rapid response, recent events at Salmon Lake have given us important, concrete evidence of the critical importance of building a strong, sustainable, statewide early detection team. Thanks to all of you who have participated in one or more Invasive Plant Patrol (IPP) workshops and have spent time monitoring the waters of Maine for aquatic invaders, we are well on track in this regard.

Consider the following...

- Nearly every known infestation in the State of Maine has been detected by an informed and alert citizen.
- Roughly seventy percent of the invasive aquatic plant survey activity being conducted in Maine is now being done by trained volunteers.
- The number of waterbodies with reported surveys has increased nearly four-hundred percent since the IPP program began.

There is, of course, much yet to be done. There are still thousands of lakes and ponds, and tens of thousands of miles of stream habitat in Maine that have never been surveyed for the pres-

ence of aquatic invaders, and to do the job right, *all* Maine waters should be surveyed routinely and repeatedly for the foreseeable future. But every year we make significant progress. Every year more and more of you join the ranks of Maine's Invasive Plant Patrol. Every year more waterbodies are screened. With your continued involvement and support, we will continue to build upon what is already seen as one of the most effective citizen-based early detection teams in the US.

Toward this end, there is one thing that all of you could do, starting today, that would help immeasurably... and that is, simply tell others what you are doing. Spread the word to friends, family, local schools, and community, any time the opportunity arises. Describe your work as an Invasive Plant Patroller. Share what you enjoy about the work and what inspires you to continue. Send those who are interested in learning more about the threat of invasive aquatic plants, and perhaps in becoming involved in Maine's early detection effort, to the VLMP website at: [www.mainevolunteerlakemonitors/mciap/ipp](http://www.mainevolunteerlakemonitors/mciap/ipp). There are no limits to the power of this kind of face-to-face public outreach. If each of you could encourage just one person to attend an IPP workshop next year, we could double the number of trained eyes out on Maine waters in a single summer! And considering all that is at stake here in our beautiful water-rich state, that would be no small achievement.

Staff from DEP survey for invasive Eurasian water-milfoil in Salmon Lake.

## Help the VLMP Bring New Lakes Onboard

Do you know someone who might be interested in becoming a water quality monitor or plant patroller? Let us know and we'll send you information and an application form to pass along. Or we can contact them directly if you'd prefer. We can also send you a packet of information including an article for your lake association newsletter to help recruit new volunteers.

The VLMP relies primarily on word of mouth from individuals and associations to recruit new volunteers and bring new lakes into the program. We greatly appreciate your help with this effort and welcome any questions or inquiries.

SPREAD THE WORD

## Battling the Invaders

*As of March 2011, thirty-three waterbodies in Maine are known to be infested with invasive aquatic plants. Variable water-milfoil is the most widespread of these invaders, accounting for twenty-five of the infestations; a hybrid of variable-milfoil is found in two additional waterbodies. Eurasian water-milfoil is now found in two lakes, one in an unnamed quarry pond in Scarborough and the other in Salmon Lake in Belgrade. Hydrilla has been found in Pickerel Pond in Limerick and Damariscotta Lake in Jefferson. Curly leaf pondweed has been identified in West Pond in Parsonsfield and Legion Pond in Kittery, and Eurasian Naiad in Legion Pond in Kittery.*

Once an infestation has been confirmed, rapid response is crucial. The prospects for eradication (or barring that, effective management at minimum risk to the aquatic ecosystem), is greatly increased by swift, well-planned, and properly executed controls. In developing an invasive aquatic plant management plan, one of the most important questions to be answered is “How, exactly, is the invasive plant infestation to be controlled?” The principal approach in Maine—used primarily by groups currently involved in battling variable milfoil (or its invasive hybrid)—is “manual control.” Manual control methods may alternately be referred to as “non-chemical,” “physical” or “mechanical” methods. The three primary manual control methods currently being used in Maine are: manual harvesting, benthic barriers, and suction-assisted harvesting.

*Variable water-milfoil infestation in the Songo River at Sebago Lake State Park.*

Maine has taken a cautious approach to the use of aquatic herbicides to control invasive aquatic plants. Herbicides, like all pesticides, pose a definite degree of risk for people, for fish, and for the integrity of the aquatic ecosystem which depends on that body of water. Though aquatic herbicides are seen by state officials as an “effective tool,” it is the state’s position that the “benefits of using herbicides rarely exceed the risks of very real adverse ecological impacts.” Therefore, “it is only in extraordinary circumstances that the Maine Department of Environmental Protection (DEP) will support the use of herbicides.”<sup>1</sup> In recent years, the DEP has approved and overseen the use of aquatic herbicides in three specific instances—the Hydrilla infestation in Pickerel Pond in Limerick, and the Eurasian water-milfoil infestations in the unnamed gravel pit in Scarborough and Salmon Lake in Belgrade.

**IMPORTANT! – All invasive aquatic plant control projects are subject to regulation under Maine’s Natural Resources Protection Act. Before planning any control project, contact the Maine Department of Environmental Protection for specific permit requirements. All native aquatic plants are strictly protected by Maine law.**

### Manual Control Methods

Below is a brief overview of the three primary manual control methods currently being used in Maine: manual harvesting, benthic barriers, and suction-assisted harvesting. More detailed information on each method is located online at <http://www.mainevolunteerlakemonitors.org/mciap/control/>.

### Manual Harvesting (or Manual Removal)

Most of the variable milfoil management efforts currently underway in Maine involve a combination of manual control methods. Nearly all of these projects involve at least some use of the method known as manual harvesting. Manual harvesting is a useful technique for removing scattered individual plants and controlling small, infested patches. With manual harvesting, plants and their root systems are individually removed from the infested area, collected, and transported away from the waterbody for disposal. As even

tiny plant fragments can generate new plants, it is very important when using manual harvesting that every attempt is made to remove all plant and root fragments from the project site.

*Jim Chandler, using manual harvesting to control variable milfoil in Lily Brook, surfacing with a bag full of milfoil.*

The means by which the plants are approached, handled, and even the way in which they are disposed of may vary, but the basic concept remains the same. Think “weeding the garden by hand (or with hand tools).” Now think “weeding the garden under several feet of water.” This should give you a pretty good sense of the work. Depending on the water depth, the work is done by waders, boaters, snorkelers and/or SCUBA divers. Though manual harvesting is a labor-intensive process, if done with care it is a “species selective” technique that causes minimal impact to other native species in the vicinity of the control activity. However, despite the level of care and thoroughness, it is nearly impossible to see and remove every stem and root fragment in the infested area. For this reason, ongoing monitoring of management sites and routine control activity is essential.

### **Benthic Barriers (also called Benthic Mats or Bottom Barriers)**

Placement of benthic barriers is another labor-intensive, but effective, method for controlling invasive milfoils. Benthic mats are particularly useful in treating small to moderate sized patches of dense growth. They are used to suppress invasive plant growth in high use areas such as public swimming areas. If depths are sufficient, benthic barriers may also be used to clear and define plant-free boating channels through infested areas, reducing plant-boat contact and thereby minimizing the potential for boats to spread the infestation. Controlling larger infestations with benthic barriers is possible, but given the labor and materials involved, larger control projects are generally done incrementally in stages, and in some cases may take several years to reach the desired result.

Benthic barriers may be constructed in various shapes and sizes, using a variety of materials and systems for weighting the mats down. Their basic function, however, is to lay “flat” on the bottom of the lake, pond, or stream, covering the infested area, preventing plants underneath from receiving sunlight, thereby killing them. (Returning to the garden analogy . . . think mulch). The mats are left in place long enough to kill the plants (generally four to six weeks, though in some cases, the mats may be left in place for longer periods). Manual harvesting is often used in tandem with the placement of benthic barriers to control any “outliers” and plants that find their way out from under the mats around the edges. One significant advantage with the use of benthic barriers is that the plants in the treated area are, by and large, killed. The “almost impossible” challenge of extracting every root hair from the substrate (as is necessary to completely kill a plant through manual harvesting) is largely eliminated when this method is properly employed. One disadvantage is that benthic mats are not “species selective” and may cause “collateral damage” to any native flora and fauna that do not have the means to escape out from under the mats.

*Photo by Nikki Leam  
Team installing benthic barriers to control variable milfoil in Lily Brook.*

### **Diver Assisted Suction Harvesting (DASH)**

Suction harvesting is the least frequently used, of the three manual control methods now employed in Maine. It is a relatively expensive and cumbersome control option. However in certain circumstances--such as large, widespread infestations--suction assisted harvesting is proving to be an important

management tool. Groups in Maine utilizing this method have shown enormous industry and innovation in developing the required technology and techniques. As the fine-tuning of the process proceeds and more “rigs” come on line, it is likely that the use of suction-assisted harvesting in Maine will expand.

*Little Sebago Lake Association has developed two floating work stations (dubbed HIPPO I and HIPPO II) to support their suction assisted harvesting activity*

Suction harvesting is “manual harvesting” (see above) with the added advantage of a highly efficient way to get the plants to the surface where they are collected for disposal. Rather than swimming the plants to the surface in mesh bags, divers extract plants by hand as above, and then feed the plant material directly into a suction tube for rapid transport to the work platform at the surface (generally a pontoon boat or barge). From the hoses, the plants and any sediments clinging to the plants, are pumped through some form of strainer system, then piled or bagged. The sediment-laden water that comes along with the plants is either returned directly to the waterbody, or (better) is put through another system that removes sediment particles or allows them to settle out.

Plant fragmentation is a concern with all of these manual control methods, but with diver-operated suction harvesting the potential for

fragmentation is moderately high. Use of careful technique and fragment barriers can significantly reduce the creation and escape of fragments from the work area.

---

1. Keynote Presentation at the Seventh Annual Maine Milfoil Summit by Commissioner David P. Littell, Maine Department of Environmental Protection.

# The Use of Herbicides to Control Invasive Aquatic Plants: Questions and ~~Answers~~ *More Questions...*

Roberta Hill, Program Director, VLMP Center for Invasive Aquatic Plants

*Thirty-three waterbodies in Maine are known to be infested with invasive aquatic plants. Variable water-milfoil is the most widespread of these invaders, accounting for twenty-five of the infestations; a hybrid of variable-milfoil is found in two additional waterbodies. Eurasian water-milfoil is now found in two lakes, one in an unnamed quarry pond in Scarborough and the other in Salmon Lake in Belgrade. Hydrilla has been found in Pickerel Pond in Limerick and Damariscotta Lake in Jefferson. Curly leaf pondweed has been identified in West Pond in Parsonsfield and Legion Pond in Kittery, and Eurasian Naiad in Legion Pond in Kittery.*

The increased awareness of existing or new infestations, the alarming rate of advance of some invasive populations, and the significant challenges that arise when one takes on the task of controlling aquatic invaders have all contributed to a growing sense of urgency, perhaps even something more akin to panic. It is not surprising that, in the midst of this deepening climate of concern, the hunt should intensify for the proverbial "silver bullet" that will, if not kill the offending invader once and for all, at least diminish it to the point that it no longer poses a significant threat. It is in this context that some are now asking about the possibility of expanding the use of aquatic herbicides to control the invaders. Some commonly asked questions are "Why can't we just kill the plants with herbicides?" or "Other states routinely use aquatic herbicides to control invasive aquatic plants: Why aren't herbicides more widely used in Maine?"

The purpose of this article is to take a careful look at the prospect of expanding the use of aquatic herbicides in Maine—and to ask some of the questions that will surely arise as we, the citizens of Maine, begin to consider the pros and cons of such a course of action. How are aquatic herbicides currently being used in our state? What is the rationale behind Maine's current "cautious" approach to the use of aquatic herbicides? Are aquatic herbicides safe? Are they effective?

The intention here is not to attempt to provide *answers* to these questions, because to some extent there are no clear answers. Rather, it is to illuminate some of the complexities inherent in the questions themselves, and to suggest the types of questions that should be asked if we wish to ensure the best decisions moving forward. The primary goal of this article, in other words, is to simply get the ball rolling on a critically important public discussion; one that ultimately may impact all of us who have a special place in our hearts for Maine's lakes, ponds and rivers.

**Question 1: How are aquatic herbicides currently being used in Maine? What is the rationale behind Maine's current "cautious" approach to the use of aquatic herbicides?**

Controlling hydrilla in Pickerel Pond with aquatic herbicides  
(Photo courtesy of MDEP)

To treat waters of the State with an herbicide one must apply for, and receive, a waste discharge license from the Maine Department of Environmental Protection. Licenses are approved (or not) on a case-by-case basis. The risks and benefits of using a particular herbicide are weighed against the risks and benefits of not doing so. The risks and benefits associated with alternative methods of controlling the particular infestation must also be considered.

The rationale behind Maine's measured and cautious approach to regulating the use of aquatic herbicides was stated succinctly by Maine Department of Environmental Protection Commissioner, David Littell, in his keynote address at the 2006 Milfoil Summit: "Herbicides, and all other pesticides for that matter, pose a definite degree of risk for people, for fish, and for the integrity of the aquatic ecosystem which depends on that body of water." Though state officials are currently using aquatic herbicides to control invasive plants in two instances as described below, it is the state's position that the "benefits of using herbicides rarely exceed the risks of very real adverse ecological impacts." Therefore "it is only in extraordinary circumstances that DEP will support the use of herbicides."<sup>1</sup>

Since 2003, Maine DEP has approved and overseen the use of aquatic herbicides in four specific instances—the Hydrilla infestation in Pickerel Pond in Limerick, the Eurasian water-milfoil infestation in the unnamed gravel pit in Scarborough, the Eurasian water-milfoil infestation in Salmon Lake in Belgrade, and the Hydrilla infestation in Damariscotta Lake in Jefferson. According to former Commissioner Littell, all four of the infestations are seen as unique. All occur in small ponds less than 50 acres in size or small coves, "small enough to manage effectively." Both species are considered extremely serious invaders, widely recognized by biologists as among the "most tenacious, most costly, and most environmentally damaging plant species in North America." Containing these two particular invaders and "preventing any opportunity for them to take hold elsewhere in Maine—is", according to the DEP, "the primary benefit of using herbicide on these four ponds."<sup>2</sup>

Maine DEP's Paul Gregory has explained that the decision to apply herbicides in these four unique situations was something like deciding to treat an aggressive [and in this case highly infectious] disease with chemotherapy, a toxic regimen that interacts with the whole system being treated, not just those parts you are attempting to destroy ... "very serious medicine to be used only when all other, less risky treatments have been ruled out as inadequate to the task."

## Question 2: Are aquatic herbicides safe?

All herbicides legally used in the United States for controlling aquatic plants must be "registered for use" by the US Environmental Protection Agency (EPA). According to the EPA's own definition, pesticide registration is the "process through which EPA examines the ingredients of a pesticide; the site or crop on which it is to be used; the amount, frequency and timing of its use; and storage and disposal practices. EPA evaluates the pesticide to ensure that it will not have unreasonable adverse effects on humans, the environment and non-target species."<sup>3</sup> It should be noted that the EPA definition does *not* say there will be "no adverse effects." It says that any possible adverse effects will not be "unreasonable." So here is one of those niggling complexities that gives rise to more questions...Who gets to define the term "unreasonable"? Under what conditions is an *adverse* effect deemed "reasonable?"

Although pesticide registration is scientifically rigorous it does not guarantee that a product is completely safe. Significant gaps in the research remain. Roy Bouchard, biologist with the Maine Department of Environmental Protection, points to one of the gaps. "I know of very few long-term studies of the effects of herbicide use on ecosystems. Repeated use of herbicides for long term management of aquatic vegetation can fundamentally shift how the system operates, and how the rest of the plant and animal community that depend on aquatic vegetation responds in the long term. Herbicides may not kill organisms such as invertebrates or fish directly, but little is known about what will happen to [these organisms] and their habitat over time."

Part of the problem lies in the fact that for organisms other than humans, the registration process is primarily concerned with "acute toxicity," the study of how much of the product in question it takes to kill this life form or that. When it comes to "sub-lethal effects," especially on creatures other than mammals, very little is known. And what is known is not entirely reassuring. Recent studies on

endangered Pacific salmon, for example, have suggested there may be sub-lethal or behavioral effects from pesticides. Another problem comes from the way the data is generated. Most of the “effects” are extrapolated from short term, high dose tests conducted on a small number of species. A number of epidemiological studies suggest that the short term animal studies tend to underestimate the effects on humans, and the same studies support the notion that many sub-lethal effects aren't being predicted at all.

Another area where knowledge is scarce surrounds the question of how different compounds interact with each other in the environment. What are the risks to the environment and human health when herbicides applied directly into our water resources are combined with other toxic materials released into the watershed from forestry, agriculture, and home lawn and garden activities? The EPA estimates that there are currently about 87,000 “chemicals in commerce” in the US. Do the math and you will soon understand the complexity inherent in properly assessing all possible interactions between all possible combinations of these chemicals in the environment.

Which begs another question...do we even know which chemicals are already present in our lakes and rivers, and at what concentrations? Following a ten-year national study of rivers and aquifer systems conducted by the EPA and the US Geological Survey (USGS), a report was recently released describing the occurrence of pesticides in our nation's waters. The report concludes that pesticides (a broad group of chemicals that includes herbicides) are “typically present throughout the year in most streams in [developed] areas of the Nation...at concentrations that may affect aquatic life or fish-eating wildlife.”<sup>4</sup>

The EPA/USGS study also discovered that detected pesticides seldom occur alone; rather they almost always occur as complex “mixtures.” Acknowledging that very little is known about the potential toxicity of such mixtures, the researchers ultimately conclude that “the study of mixtures should be a high priority.”

Most stream samples and about half of the well samples contained two or more pesticides and frequently more. The potential effects of contaminant mixtures on people, aquatic life, and fish-eating wildlife are still poorly understood and most toxicity information, as well as water-quality benchmarks used in the study, has been developed for individual chemicals. The common occurrence of pesticide mixtures, particularly in streams, means that the total combined toxicity of pesticides in water, sediment, and fish may be greater than that on any single pesticide compound that is present. Studies of the effects of mixtures are still in early stages, and it may take years for researchers to attain major advances in understanding the actual potential for effects. Our results indicate, however, that studies of mixtures should be a high priority.<sup>5</sup>

This call for a better understanding of the “potential effects” of herbicides—and in particular the potential effects of herbicides on public health—has been voiced here in Maine as well. Roughly one third of Maine's citizens get their drinking water from “surface waters” of the State (lakes, ponds and rivers). What impact, if any, would loosening the restrictions on the use of aquatic herbicides have upon Maine's drinking water supply? Echoing some of the concerns described above, the Maine Water Utilities Association (MWUA) has taken a clear position on the issue.

Like all surface waters in the state, [those that serve as] water supplies are threatened by the spread of invasive aquatic plants. As drinking water suppliers, our primary concern is for potential impacts that the spread of these organisms could have upon human health and the long-term safety of the drinking water supply. . . The use of aquatic herbicides to control invasive plant infestations has become common [in the United States]. Despite the advertisements that claim these products leave “no residue” and have shown “no adverse effects,” there are still many questions left unanswered about the long-term health risks associated with these agents, for both humans and wildlife.<sup>6</sup>

In making its case, MWUA points to another outstanding gap in the research concerning the safety of aquatic herbicides.

One significant question yet to be answered is whether or not the chemicals currently used to control aquatic plants are endocrine disruptors. Endocrine disruptors are synthetic chemicals that interfere with the operation of the endocrine system, the system of hormones that regulates an organism's development, growth, reproduction and behavior. Because they may interfere with reproductive function, the adverse affects of these compounds may not be immediate but, instead, passed from one generation to the next . . . At present, the research focused on the effects of these compounds on human endocrine systems is incomplete and inconclusive. According to the EPA, "there currently is not enough scientific data available on most of the estimated 87,000 chemicals in commerce to allow us to evaluate all potential risks."<sup>7</sup>

After consideration of the potential, as yet unknown risks associated with the use of aquatic herbicides, MWUA argues for erring on the side of caution, taking the position that "No herbicides should be used in a public drinking water supply."<sup>8</sup> And if aquatic herbicides are to be used in the *watershed* of a public drinking water supply, MWUA suggests the following conditions should apply:

1. The compound to be used has undergone adequate testing to determine the short and long-term health effects on human health, including the compound's potential to disrupt endocrine systems.
2. The chances for total eradication by this method are excellent, reducing the need for repeated applications.
3. All water utility customers are properly notified of the intended action, given an opportunity to comment, and concerns can be adequately addressed.<sup>9</sup>

### Question 3: Are aquatic herbicides effective?

There is a good deal of research and numerous case studies supporting the claim that aquatic herbicides are effective tools in controlling or "knocking back" aquatic plants. But *eradication* of invasive aquatic plant species by *any* means, including by the use of herbicides, is rare indeed.

Case in point: Hydrilla in the state of Florida. Hydrilla, now in more than 40% of Florida's public waters, is reported to be the most abundant submersed aquatic plant in the state. Despite one of the most aggressive (and expensive) invasive plant management programs in the country, involving an extensive use of aquatic herbicides, this "worst of the worst" invader appears in more Florida waterbodies every year.

*Hydrilla infestation in Pickerel Pond, 2002*

One of the challenges of Hydrilla, is that the herbicides commonly used to control it do not affect Hydrilla seeds, tubers and turions (small vegetative buds capable of reproduction) and repeated applications are needed to control regrowth. The Hydrilla in Pickerel Pond, for example, has been treated with fluridone (the herbicide of choice for this invader) every year since 2003. It is not yet known how many additional treatments may be needed before the "tuber bank" in the sediments will be depleted to the point that regrowth can be handled by manual control methods alone.

Another problem with respect to the efficacy appears to be the result of a phenomenon known as "herbicide resistance." When a plant loses its sensitivity to an herbicide over time through the process of genetic selection, it is said to have become "resistant"

to that herbicide. We have been aware of this phenomenon for decades in agricultural systems, so it is not really surprising to learn that evidence is now mounting to show that some aquatic plant species are developing a similar resistance.

An article in the spring 2006 issue of *Aquatics*,<sup>10</sup> the journal of the Florida Aquatic Plant Management Society, reports that some Hydrilla populations in Florida have developed resistance to fluridone; meaning that the herbicide is no longer effective in controlling Hydrilla in these lakes. The authors suggest various strategies for minimizing the potential for resistance, including: avoiding the repeated use of herbicides that kill plants by way of the same "mode of action," alternating the types of herbicides used, and using other non-herbicide methods, such as mechanical and/or manual control, when feasible.

What is the extent of aquatic herbicide resistance nation wide? What are the possible implications of this resistance over time? As for the suggestion that "alternating herbicides" may be one solution to the resistance problem, how does this strategy square with the USGS/EPA caution regarding "herbicide mixtures"? Again, there are many questions to be asked, and limited data with which to answer them.

There seems little doubt that the discussion and debate concerning the question of the "proper" use of aquatic herbicides in Maine will be with us for some time. It is a discussion worthy of careful attention, thoughtful consideration and widespread involvement.

When you come to a difficult crossroad, it is always a good idea to take a few steps back where you can ponder the longer and broader view. Maine proudly claims that ours is the state where life is "as it should be." One assumption inherent in that claim is that we have an environmental condition that sets us apart from other states, and our unique environmental heritage is something to be valued and protected. The shorelines of most of Maine's lakes and streams are vastly different, aesthetically and ecologically, from shorelines in most other states in our country. This is in part due to the fact that we have had less development pressure. But it also stems from having the advantage of learning from the experiences of others who have already borne those higher pressures. Maine's Shoreland Zoning codes, almost unique in the nation, are a prime example of benefits reaped from lessons gleaned from "away." Maine's cautious approach to the use of aquatic herbicides is another example.

Which brings us back full circle to one of the original questions asked here, "Other states routinely use aquatic herbicides to control invasive aquatic plants. Why aren't herbicides more widely used in Maine?" Perhaps the best way to answer this question is to pose another... "Just because other states allow the widespread use of herbicides (as well as significant alterations of shoreline and wetland habitat etc.) is that a good reason for Maine to follow suit?"
